This book adopts a novel approach: procedures: instead of discussing the diagnostic categories of neurological syndromes, it focuses on the symptoms of common neurological presentations (especially in the emergency room or on the ward), and the diagnostic hypotheses that can be validated or rejected case by case as a result. Each chapter covers one of the main symptoms of emergencies in neurology – from transient consciousness disturbances to focal deficits, acute muscular disorders, respiratory insufficiency in neurological disorders, headaches, delirium, seizures and epileptic status, para-and tetraplegia, and head trauma, to acute functional disorders – and includes tables and figures to allow readers to gain a quick and easy, yet comprehensive overview of the topic. The book guides readers through various scenarios generated by the onset of symptoms, the clinical tools for differential diagnostics, and the principles of acute and post-acute phase therapy, managed by decision algorithms supported by the most recent scientific evidence. The resulting preceudural profile – created through the collaboration of over 80 specialists in neurology or other disciplines – makes this text a valuable tool for neurologists, neurology residents and allied professionals in their daily clinical practice, as well as medical students.

Diagnostic and Treatment Algorithms in every chapter Boxed element for “when to refer” Diagnostic Tests-What to order is discussed, not what to consider ordering Medical Treatment includes drugs and dosages in tabular format Icons to lead the reader to the content they need quickly Clinical COLOR photos and clear, didactic diagrams on every page Consistent headings among chapters covering similar topics This book is a complete guide to paediatric neurology for clinicians. Beginning with an overview of potential pitfalls in neurological examination of children, the following chapters discuss the diagnosis and management of numerous neurological disorders that may be encountered in daily paediatric practice. Topics covered include cerebral palsy, Guillan-Barré Syndrome, febrile seizures, muscle disorders, cerebral edema, epilepsy, neurogenic bladder dysfunction and much more. Each section is presented with an emphasis on the importance of accurate clinical examination, and covers all the latest developments and management strategies. With prevalence figures close to 0.2% at birth and rising to 0.35% during adolescence, hearing loss is the most frequent sensory impairment in childhood. This silent handicap has to be actively sought for without delay as it will seriously interfere with the development of speech, language, cognitive and socio-emotional behavior. Objective physiological techniques (evoked potentials, oto-acoustic emissions, tympanometry) combined according to the cross-check principle allow early diagnosis. Objective testing yields invaluable information about the mechanism of the loss and the contribution of disruption of the neural code to the handicap. Among the acquired causes, cytomegalovirus (CMV) infections plays a major role and may take elusive forms. Aminoglycoside ototoxicity has a genetic determinant. Meningitis can lead to rapid endocochlear ossification prompting for rapid cochlear implantation. Genetic causes account for more than 60% of congenital hearing loss, new genetic causes being discovered at an amazing rate. The high number of genetic entities and their huge heterogeneity among them requires guidelines for requesting genetic testing when desirable. Several syndromes prone to request neuropediatricians' attention as an early diagnosis followed by specific treatment can considerably limit the ensuing handicap. Whatever the type of assistive device fitted (amplifying hearing aid or cochlear implant) and the importance of associated handicaps, a multidisciplinary rehabilitation combined with educated parental commitment is necessary for optimal results.

The fundamental goal of the revised edition of this acclaimed text is to provide comprehensive, practical, and straightforward information about the developing nervous system that is as relevant to those embarking on careers in pediatric neurology as it will be to the experienced practitioner who cares for infants, children, and adolescents. New to this edition are chapters on tumors of the nervous system, autism and related conditions, and practice parameters in child neurology.

This book aims to simplify and demystify some of the common problems in pediatric neurology especially encountered by the general pediatricians and pediatric students (both undergraduates and postgraduates). It tries to describe a practical approach towards the diagnosis and treatment of various neurological conditions which would prove extremely useful in day to day clinical practice. This book, titled Algorithms in Pediatric Neurology intends to enable the ordinary pediatrician to recognize many disorders in a simplified manner and give practical suggestions in their management. These algorithms are based on the concept of listening, watching and thinking before initiating treatment. Pediatric neurology has come a long way. There was a time when a pediatrician's best advice was to tell the parents to simply wait and let the child outgrow his problems. Today magnetic resonance imaging, genetics and basic science related to the understanding of complex illnesses have changed the way we handle these problems. However, the clinical approach to most problems can be further simplified. It is in the larger good of empowering the general pediatrician and student of pediatrics to try to look at and understand pediatric neurology problems.

Teaches symptom-oriented approaches to the most common problems facing trainee neurologists, emphasizing patient history and integrating evidence-based and experience-based strategies.

This is the only comprehensive collection of algorithms which exclusively addresses hematologic and oncologic problems affecting neonates, children and adolescents. Examining clinical problems which challenge the pediatrician, general practitioner and family practice physician, each algorithm utilizes a concise, step-by-step approach based upon clues from the history, physical examination and laboratory studies. The algorithms addressing differential diagnosis clearly distinguish between the most common etiologies, those that are less frequent, and finally some that are rare but important to recognize. The 51 topics include evaluation of anemia, sickle cell anemia, thalassemia, hemolytic anemia, the bleeding child, thrombocytopenia and other platelet disorders, hemophilia, leukocyte disorders, leukemias, lymphadenopathy, splenomegaly, approaches to mass lesions in the mediastinum, abdomen, pelvis, bones and soft tissues as well as approaches to potential emergencies such as tumor lysis and superior vena cava syndromes. The oncology topics emphasize diagnostic approach and management of complications, and not the details of chemotherapy. All algorithms are presented with a page of explanatory notes and a list of selected reading. Pediatricians, family physicians and general practitioners will find this book very helpful in managing problems in their practices. Trainees in pediatric hematology will find it a useful tool in developing approaches to solve the problems they will encounter, and pediatric hematologists/oncologists will find it useful as a teaching tool.

Newly updated to reflect recent discoveries, fifth edition of Introduction to Clinical Neurology covers all the take home points beneficial to everyone who relies on this quick and handy guide. This book focuses on the "how" and "why" of clinical neurology. It includes extensive

factual material about individual disease processes, but the emphasis is on information that is important for understanding why patients with neurologic conditions are managed the way they are. This book covers what clinicians need to know in order to assess and manage the patients they will encounter in general medical practice, including the application of a logical approach to diagnosis, neurologic examination and how to interpret the findings, and the management of specific disease categories and symptoms. A highly accessible and engaging text, this is the go-to in all things neurology.

This book provides recommendations for evaluation and therapy in the area of acute pediatric neurology; these are presented didactically with frequent use of illustrations and algorithms. Chapters in the first part of the book discuss presenting symptoms of acute neurological conditions. The second part of the book covers major areas of acute pediatric neurology and each of these chapters has three key elements: description of presenting symptoms; recommended assessments; and recommended interventions. Acute Pediatric Neurology provides an accessible, clinically focused guide to assist physicians in the emergency ward or intensive care unit in decisions on diagnosis and therapeutic interventions in all major acute pediatric neurological diseases.

The fourth edition of classic resource has been completely rewritten and updated to give a full account of the many advances in the field. This book continues to be the only reference in paediatric neurology organized by 'chief complaint', making it extremely useful in the clinical environment. For every presenting symptom, clear algorithms guide readers through evaluation and management, one step at a time. Defines each complaint by age at onset, course of illness, discriminating features, and treatment options Excellent preparation for Paediatric Neurology exams Includes a complete differential diagnosis for each presenting complaint, tabulated for easy reference Cross-references for disorders with diverse initial features allow fast access to relevant information Clearly designed algorithms allow readers to work through the complex area of neurodegenerative disorders Numerous new tables put up-to-the-minute data at the readers' fingertips The Headache chapter incorporates all of the latest drugs Bibliographical references incorporate new citations to a wide range of state-of-the-art sources

Malformations of cortical development, especially focal cortical dysplasia in infants and children, and hippocampal sclerosis in adolescents with epilepsy are frequent lesions, but they are overlooked on standard MRI. In infants, errors in the interpretation of MRI in epilepsy can be attributed to MRI signal changes due to ongoing myelination. Poor technique, perceptual misses, incomplete knowledge and poor judgment are, however, other likely sources of errors when reading MRIs. This review covers MRI search strategies, i.e., how to conduct MRI examinations in epilepsy and what to expect in the structural MRI of an infant or child with focal epilepsy. Exploiting increased sensitivity, false positive results can be avoided in the light of a clinical hypothesis, possibly isolating a localized brain area by seizure semiology, EEG, and sometimes PET prior to MR reading.

The child is neither an adult miniature nor an immature human being: at each age, it expresses specific abilities that optimize adaptation to its environment and development of new acquisitions. Diseases in children cover all specialties encountered in adulthood, and neurology involves a particularly large area, ranging from the brain to the striated muscle, the generation and functioning of which require half the genes of the whole genome and a majority of mitochondrial ones. Human being nervous system is sensitive to prenatal aggression, is particularly immature at birth and development may be affected by a whole range of age-dependent disorders distinct from those that occur in adults. Even diseases more often encountered in adulthood than childhood may have specific expression in the developing nervous system. The course of chronic neurological diseases beginning before adolescence remains distinct from that of adult pathology – not only from the cognitive but also motor perspective, right into adulthood, and a whole area is developing for adult neurologists to care for these children with persisting neurological diseases when they become adults. Just as pediatric neurology evolved as an identified specialty as the volume and complexity of data became too much for the general pediatrician or the adult neurologist to master, the discipline has now continued to evolve into so many subspecialties, such as epilepsy, neuromuscular disease, stroke, malformations, neonatal neurology, metabolic diseases, etc., that the general pediatric neurologist no longer can reasonably possess in-depth expertise in all areas, particularly in dealing with complex cases. Subspecialty expertise thus is provided to some trainees through fellowship programmes following a general pediatric neurology residency and many of these fellowships include training in research. Since the infectious context, the genetic background and medical practice vary throughout the world, this diversity needs to be represented in a pediatric neurology textbook. Taken together, and although brain malformations (H. Sarnat & P. Curatolo, 2007) and oncology (W. Grisold & R. Soffietti) are covered in detail in other volumes of the same series and therefore only briefly addressed here, these considerations justify the number of volumes, and the number of authors who contributed from all over the world. Experts in the different subspecialties also contributed to design the general framework and contents of the book. Special emphasis is given to the developmental aspect, and normal development is reminded whenever needed – brain, muscle and the immune system. The course of chronic diseases into adulthood and ethical issues specific to the developing nervous system are also addressed. A volume in the Handbook of Clinical Neurology series, which has an unparalleled reputation as the world’s most comprehensive source of information in neurology International list of contributors including the leading workers in the field Describes the advances which have occurred in clinical neurology and the neurosciences, their impact on the understanding of neurological disorders and on patient care

This book is a practical guide for primary care physicians, psychiatrists, and other non-neurologist clinicians who encounter patients with neurologic problems. The book begins with overviews of neurologic symptoms, the neurologic examination, diagnostic tests, and neuroradiology, and then covers the full range of neurologic disorders that non-neurologists encounter. Chapters follow a consistent structure with key elements highlighted for quick scanning. Each chapter begins with Key Points and includes Special Clinical Points, Special Considerations in the Hospitalized Patient, and When a Non-neurologist Should Consider Referring to a Neurologist. Each chapter ends with an Always Remember section emphasizing the most important practical issues and a series of self-study questions.

There has been important progress in the identification of antiepileptic compounds and their indications in children over the past 15 years: their number has doubled and specific pediatric trials are being performed to document their effect according to seizures and syndromes as well as their tolerability in pediatrics. The improved understanding of pharmacokinetics and drug–drug interactions has helped to optimize treatment. Specific issues specific of infants have also been studied although new antiepileptic drugs are still dramatically lacking for this age group. Before reaching a syndromic diagnosis, the choice of a first-line agent goes to compounds with the largest range of efficacy and least identified risks. Subsequent choices are mainly based on the epilepsy syndrome and seizure type in addition to good clinical practice to determine dose, adverse effect profile, risk of aggravating seizures and drug interactions, clinician's experience, cultural habits, and availability of drugs. If there are several options, preference is given to the compound that exhibits the best risk/benefit ratio, or the most rapid titration when seizure frequency is the major issue. For new antiepileptic compounds, price is often a limiting factor in countries with poor insurance coverage. Third generation anti-epileptic drugs are emerging which also seem to be promising.

Cortical generators of epileptic and certain physiological activity can be localized noninvasively by magnetoencephalography (MEG). MEG detects weak magnetic fields produced by the postsynaptic currents of pyramidal cortical cells in sulcal walls. Unlike EEG, MEG signals are not distorted by edema or bone defects, and unlike fMRI, abnormal hemodynamics do not alter the MEG. The patient's head is centered inside a helmet housing over a hundred magnetic field sensors. Cortical generators of MEG signals are determined with a useful spatial resolution and an excellent time resolution, which enable tracking of brain activity in successive points of, for example, an epileptic network. MEG sources can be co-registered and visualized on magnetic resonance images (MRI). MEG is highly sensitive for the detection of interictal epileptic discharges, and present techniques allow some degree of head movements enabling ictal recordings also. MEG is also useful for localizing the somatosensory, visual, and language areas before tailored surgery in the vicinity of eloquent cortex. In conjunction with other noninvasive modalities MEG provides nonredundant data in one-third of epilepsy surgery patients. Clinical MEG utilization is mainly focused on presurgical localization of the epileptogenic zone and eloquent cortex in epilepsy surgery candidates, including patients with Landau–Kleffner syndrome. However, MEG is also an excellent noninvasive tool to study the source distribution in childhood epilepsy syndromes and epileptic encephalopathies.
